

## M3-L1 Problem 1 (6 points)

```
In [5]: import numpy as np
import matplotlib.pyplot as plt
```

### Sigmoid function

Define a function, `sigmoid(h)`, which computes and returns the sigmoid  $g(h)$  given an input  $h$ . Recall the mathematical formulation of sigmoid:

$$g(h) = \frac{1}{1 + e^{-h}}$$

```
In [6]: def sigmoid(h):
# YOUR CODE GOES HERE
return 1/(1 + np.exp(-h))
```

### Transformation function

In logistic regression, we transform the input before applying the sigmoid function. This transformation can take many forms, but here let's define a function

`transform_quadratic(x, w)` that takes in an input  $x$ , and a weight vector  $w$ , and returns the sum  $w_0 \cdot 1 + w_1 \cdot x + w_2 \cdot x^2$ .

```
In [7]: def transform_quadratic(x, w):
# YOUR CODE GOES HERE

return w@np.array([1, x, x**2])
```

### Example

Now, we will use both `sigmoid()` and `transform_quadratic()` in a logistic regression context.

Suppose a logistic regression model states that:

**[Math Processing Error]** for  $g(h)$  the sigmoid function and  $w = [4, -3, 2]$ .

Use the functions you wrote to compute  $P(y = 1 \mid x = 1.2)$  and  $P(y = 1 \mid x = 7)$ . Print these probabilities.

```
In [8]: w = [4, -3, 2]
for x in [1.2, 7.]:
    P = sigmoid(transform_quadratic(x, w))
    print(f"x = {x:3} --> P(y=1) = {P}")
```

```
x = 1.2 --> P(y=1) = 0.9637362836253517
x = 7.0 --> P(y=1) = 1.0
```
