M2-L1 Problem 1 (5 points)

In this question you will perform linear least squares regression on a very small dataset of 3 points. First, load and plot the data by running the following cell.

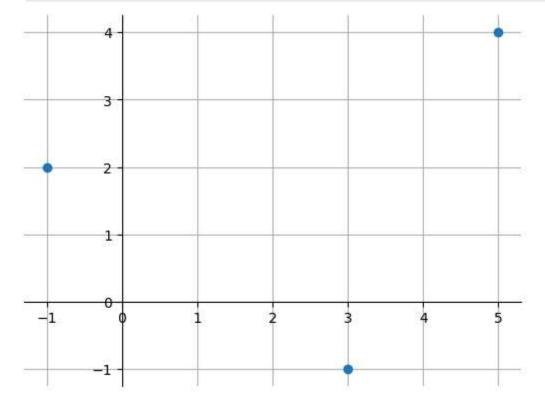

The variables provided are:

- x: 3x1 input data
- y: 3x1 output data

```
import numpy as np
import matplotlib.pyplot as plt
import seaborn as sns

x = np.array([[-1, 3, 5]]).T
y = np.array([[2, -1, 4]]).T

fig, ax = plt.subplots()
plt.plot(x, y,'o')
ax.spines['left'].set_position(('data', 0))
ax.spines['bottom'].set_position(('data', 0))
sns.despine()
plt.grid()
plt.show()
```

Construct a design matrix

For 1-D linear regression, the design matrix must contain not only a column of input x-values, but also a 'bias column' -- a column of ones (to allow the regression line to have an intercept).

The next step is to construct the design matrix x by concatenating a column of ones to the given input x. This has been done for you below:

```
In [2]: bias = np.ones_like(x)

X = np.concatenate([x,bias],1)

print("Design Matrix:\n",X)

Design Matrix:
   [[-1 1]
   [ 3 1]
   [ 5 1]]
```

Solving for regression coefficients

Now that we have the design matrix X and the output y, we can solve for the coefficients w such that $Xw \approx y$ using:

$$w = (X'X)^{-1}X'y$$

Note that you can use the following in Python:

- @ for matrix multiplication
- np.linalg.inv(A) for inversion of matrix A
- A.T for transpose of a matrix A
- b.reshape(-1,1) to treat 1D array b as a column (you will need to do this for
 y)

Your line's slope should be pprox 0.18 and your y-intercept should be pprox 1.25.

```
In [3]: # YOUR CODE GOES HERE
    # Get coefficients w
    w = np.linalg.inv(X.T@X)@X.T@y
    print("Linear Coefficients:\n", w)

Linear Coefficients:
    [[0.17857143]
    [1.25]]
```

Making predictions

Now that we have the coefficients, we can make predictions on new data with the model.

Do the following steps:

- [Given] Sample 40 points on the interval [-3,7], such as by using np.linspace() (Append .reshape(-1,1) to convert to a column)
- [Given] Create a design matrix by adding a column of ones as done previously
- Make a prediction by multiplying your new design matrix by $\ w$. You can do matrix multiplication with the $\ @$ symbol
- [Given] Add a line to the plot showing these predictions

```
In [4]: n = 40
    x_test = np.linspace(-4,7,n).reshape(-1,1)
    bias_test = np.ones_like(x_test)
    X_test = np.concatenate([x_test, bias_test], 1)

# YOUR CODE GOES HERE
# Predict y_test

y_test = X_test@w

fig, ax = plt.subplots()
    plt.plot(x, y,'.')
    plt.plot(x_test, y_test)
    ax.spines['left'].set_position(('data', 0))
    ax.spines['bottom'].set_position(('data', 0))
    sns.despine()
    plt.grid()
    plt.show()
```
